Batch: 2023 – 2027
Academic Year 2025–2026

1. Problem Statement

In many mid-sized and large organizations, the procurement process often lacks structure and centralized control. Purchase requests are typically handled through emails, spreadsheets, or manual approvals, which leads to delays and inefficiencies. As the number of departments and vendors increases, managing procurement through such disconnected systems becomes increasingly difficult.

A major issue is the lack of visibility across the process. It is often unclear whether a purchase request has been approved, converted into an order, or fulfilled. This leads to frequent confusion and miscommunication between departments. In some cases, duplicate purchase orders are created because there is no centralized tracking mechanism.

Another critical problem is the risk of incorrect or unverified payments. Without proper validation, invoices may be processed even when the corresponding goods have not been received, leading to financial discrepancies and vendor disputes. Additionally, vendor data is often scattered, making it difficult to maintain consistency and evaluate vendor performance over time.

As organizations scale, these issues become more severe, making manual procurement systems unreliable. There is a clear need for a structured, integrated system that ensures transparency, control, and efficiency across the entire procurement lifecycle.

2. Solution Overview

SAP's Procure-to-Pay cycle provides a structured and integrated approach to managing procurement activities within a single system. Instead of handling each step separately, the entire process—from purchase request to vendor payment—is managed within SAP ERP.

The process primarily operates through the MM (Materials Management) module, with direct integration into the FI (Financial Accounting) module for accounting and payment processing. Each step generates a document that is linked to the previous one, allowing complete traceability across the procurement cycle.

Vendor management is handled through a centralized vendor master record, ensuring consistency and eliminating duplication. Purchase requisitions follow an

approval workflow before being converted into purchase orders, reducing unnecessary or duplicate purchases.
A key feature is the three-way match process, where the system verifies the purchase order, goods receipt, and invoice before allowing payment. This ensures accuracy and prevents incorrect or unauthorized payments.

3. System Architecture

The SAP Procure-to-Pay system follows a three-layer architecture, where each layer performs a specific role while remaining fully integrated with the others.

3.1 User Layer

This layer consists of end users such as procurement officers, finance team members, storekeepers, and vendor managers. They interact with the system using SAP transaction codes to perform tasks like creating purchase orders, posting goods receipts, and verifying invoices.

3.2 SAP Application Layer (MM + FI)

This is the core processing layer where business logic is executed. The MM (Materials Management) module handles procurement activities such as vendor management, purchase requisitions, purchase orders, and goods receipts. The FI (Financial Accounting) module manages accounting entries and payment processing. Both modules are tightly integrated, ensuring that every material transaction is automatically reflected in financial records.

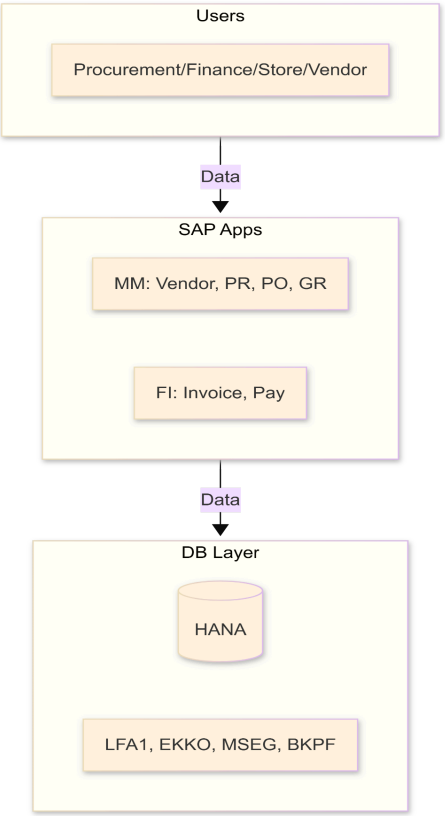

Figure 1: System Architecture (Three-Layer Model)

3.3 Database Layer

All transactional and master data is stored in the database (commonly SAP HANA). Key data includes vendor records, purchase orders, goods movement data, and financial documents. This layer ensures data consistency and provides a complete audit trail for all transactions.

4. P2P Process Workflow

The Procure-to-Pay cycle follows a sequential workflow where each step depends on the successful completion of the previous one. The process begins with vendor creation, followed by purchase requisition and purchase order generation. Once the vendor supplies the material, a goods receipt is recorded, after which the invoice is verified. The cycle concludes with payment processing.

4.1 Vendor Creation

Before any procurement activity begins, the vendor must be created in the system using T-code XK01 or MK01. The record includes general details, payment terms, and purchasing data. Once created, the vendor is assigned a unique ID used in all future transactions.
Output generated: Vendor master record with a unique vendor ID.

4.2 Purchase Requisition (PR)

A Purchase Requisition (PR) is created using T-code ME51N to request materials or services. It is an internal document that goes through an approval process before being converted into a purchase order.
Output generated: Approved PR document ready for PO creation.

4.3 Purchase Order (PO)

The Purchase Order (PO) is created using T-code ME21N and sent to the vendor. It includes details such as material, quantity, price, and delivery terms, making it a legally binding document.
Output generated: PO document issued to vendor.

4.4 Goods Receipt (GR)

Goods Receipt is recorded using T-code MIGO when materials are delivered. The system verifies the delivery against the PO and updates inventory while generating an accounting entry. Output generated: Material document and automatic FI entry.

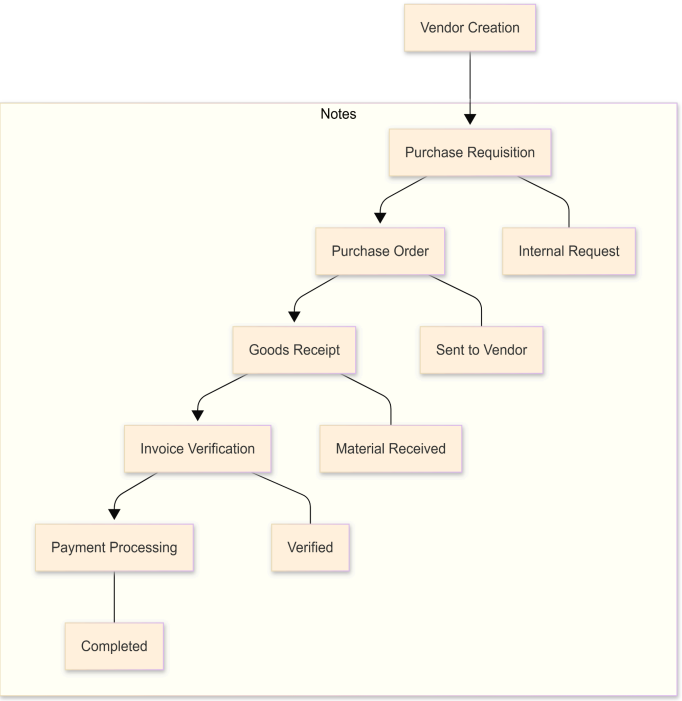

Figure 2: P2P Process Flowchart

4.5 Invoice Verification (LIV)

Invoice Verification is done using T-code MIRO. The system performs a three-way match between PO, GR, and invoice. If matched, the invoice is posted; otherwise, it is flagged for review.
Output generated: FI document with vendor liability.

4.6 Payment Processing

Payment is processed using T-code F110. The system selects due invoices, generates a payment proposal, and completes the transaction after approval.
Output generated: Payment document and cleared vendor account.

5. Key Features

One of the key strengths of SAP's P2P implementation is that it enforces process discipline rather than just automating tasks. An invoice cannot be posted without a goods receipt, and payment cannot be made without an approved invoice. These built-in controls make the system reliable for large organizations.
Another important feature is the audit trail. Every document — PR, PO, GR, invoice, and payment — is linked and time-stamped, allowing transactions to be traced back easily during audits.
Vendor management is handled through centralized master data, ensuring consistency and eliminating duplication. Updates to vendor details are automatically reflected across all transactions, while performance tracking helps in better vendor selection.
Integration between MM and FI ensures automatic accounting. Transactions such as goods receipt, invoice verification, and payment processing generate corresponding financial entries without manual intervention, maintaining a continuous and accurate accounting flow.

6. Visuals and Diagrams

The report includes diagrams for system architecture, process workflow, and a sample purchase order screen to improve understanding. These visuals are designed using simple structures such as tables, boxes, and arrows, and can be recreated using tools like MS Word, PowerPoint, or draw.io.

Figure 3: Mock Purchase Order Screen (SAP ME21N Style)

SAP ERP — Create Purchase Order (ME21N)

PO Number	4500001234	PO Date	17.04.2026
Vendor Code	V-10045	Vendor Name	Tata Steel Ltd.
Company Code	IN01	Plant	Plant 1001 - Agartala
Purchase Org.	PO01	Currency	INR

Line Items:

Item	Material Description	Material No.	Qty.	UOM	Unit Price (INR)	Total Amount (INR)
10	MS Steel Pipes 50mm	MAT-00892	200	PCS	450.00	90,000.00
20	Binding Wire 20G	MAT-01034	50	KG	120.00	6,000.00
Net Total:						96,000.00

7. Technology Stack

Since this is a conceptual and process-level implementation project, the actual tools used are documentation and modeling tools rather than live code. SAP ERP (specifically the MM and FI modules) is the core application being studied and modeled. The internal database layer is conceptually mapped to SAP HANA, though the principles apply equally to Oracle or MS SQL implementations of SAP.

For creating this report and its diagrams, MS Word was used for document formatting, while the table-based diagrams were designed within Word itself. draw.io or PowerPoint can be used to recreate the architecture and flowchart diagrams as editable vector graphics if needed. The report and diagrams were created using MS Word and basic diagramming tools such as PowerPoint or draw.io. The visuals are designed to be simple and easily reproducible.

8. What Makes This Implementation Noteworthy

This implementation highlights the importance of integration between procurement and finance functions. In many organizations, these functions operate separately, leading to inefficiencies and lack of coordination. SAP P2P addresses this by ensuring that both MM and FI modules share data in real time.
The three-way match mechanism plays a critical role in maintaining financial accuracy by ensuring that payments are made only after proper verification of purchase orders, goods receipt, and invoices.
Additionally, the structured vendor master data allows better control and consistency in vendor management, supporting more reliable procurement operations.

9. Scope for Future Improvements

Several practical extensions could further enhance this system. One improvement is the integration of a vendor self-service portal, where vendors can submit invoices and track payment status independently. This would reduce manual communication and speed up invoice processing.
Another enhancement is the use of analytics. While SAP captures large volumes of data, integrating it with tools like SAP Analytics Cloud or Power BI can provide better insights into vendor performance, lead times, and discrepancies, helping procurement teams make more informed decisions.
Additionally, AI-based anomaly detection can improve invoice verification by identifying unusual patterns that may not be caught by standard checks. This would add an extra layer of control before payments are processed.
